3.8 Type Practice (Lab 3.0)

LAB ACTIVITY | 3.8.1: Type Practice (Lab 3.0) | Full screen | 0 / 10

First, download this template and rename it `types_practice.py`:

- template.py

Write code segments that assign a single variable to value(s) read from the user for each of the following four data structures. Use the given variable names and the most appropriate data type (i.e., dictionary, list, string, tuple):

- Your *quiz scores* for this class (assume two quiz scores; prompt for each score using `score:`) — Treat scores as integers and name your variable `scores`.
- Your *system password* (For the sake of security, use a fake password here, e.g., the well-known and therefore stupidly insecure password from WarGames shown below.) — Name your variable `password`.
- The *GPS coordinates* of your dorm (You can make up coordinates for the place you'd really like to be, or use Google Maps to give you the actual coordinates) — Name your variable `dorm`.
- The *names and capitals* of your two favorite states — Name your variable `state_capitals` and design it such that when given the name of a state, it returns the name of that state's capital.

The user interaction would look like this:

```
score: 100↵
score: 95↵
password: joshua↵
latitude: 42.5↵
longitude: -87.5↵
state: Iowa↵
capital: Des Moines↵
state: Michigan↵
capital: Lansing↵
```

Here, the prompt (e.g., `score:`) is printed by the input command and the user input (e.g., `100↵`) is typed by the user. There should be no print statements in the code. For example, if we needed to create a variable for our age in years (`age`), we could use the following code.

```
age = int(input('age: '))
```

Grading

- **90% — Correctness**: Your programs should run as specified.
- **10% — Understandability**: Your programs should be easy to read.
